

Plant diseases and pests are a major constraint to agricultural production despite the various measures used to control them. Chemical control, although often effective, may pose environmental hazards and is relatively expensive, especially in developing countries where it may be completely uneconomic. Control through genetically mediated resistance to diseases and pests, is both cheap and environmentally safe and at present most diseases and pests on staple food crops are controlled through some form of resistance. One of the basic problems in the use of resistance is its frequent lack of durability; very often a type of resistance is used that breaks down after a certain period. The temporary nature of this resistance, due to the development of new strains of pest or pathogen able to overcome it, has seriously hindered the improvement of the yield potential of many crops as a continuing effort is needed to replace old cultivars whose resistance has failed, with new ones. Following Vanderplank's now classical publications (1963, 1968) which differentiated horizontal and vertical resistance, studies on several host-parasite systems have shown that different types of resistance can be distinguished genetically and epidemiologically, and on the ability of the pests or pathogens to adapt to them. A knowledge of how resistance operates at the population level has also opened up possibilities of managing relatively simple resistance types in such a way that a stable host-pathogen system can be produced with a minimum of crop loss.
